Environmental Factors
Carbon dioxide

K. Raja Reddy
Krreddy@pss.msstate.edu

Environmental and Cultural Factors Limiting Potential Yields

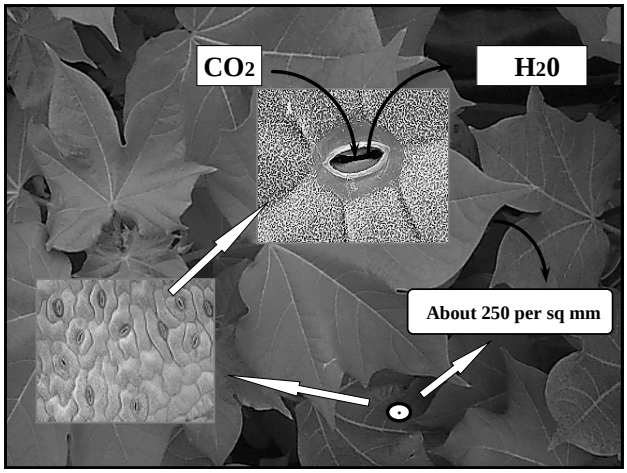
- Atmospheric Carbon Dioxide
- Solar Radiation
- Temperature (Extremes)
- Water
- Wind
- Nutrients (N and K)
- Others, ozone etc.,
- Growth Regulators (PIX)

Why are we concerned with CO2?

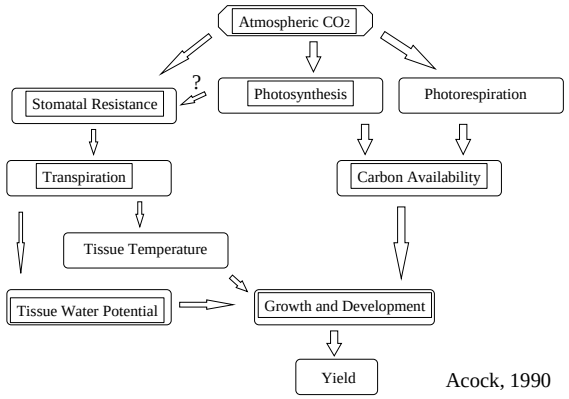
- Atmospheric CO_2 is essential for life on earth.
- Plants grow through photosynthesis, a process that uses the energy from sunlight to combine carbon dioxide (CO_2) from the air with water to make carbohydrates plus oxygen.

$$6\,CO_2 + 6\,H_2O \xrightarrow{\text{Light, Plant, Water, Nutrients}} C_6H_{12}O_6 + 6\,O_2$$

- The carbohydrates formed through photosynthesis feed not only the plants, but also almost all other organisms on earth, including those that eat the plants and those that eat the animals that eat the plants.
- Now, as the atmospheric CO_2 is rising, we are seeing almost parallel decreases in atmospheric oxygen.
- The oxygen concentration is so much higher than that of CO_2 that the decrease in oxygen from fossil fuel combustion is not a problem, but it demonstrates the connections between these two critically important atmospheric constituents.

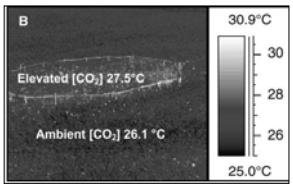


A Hierarchy of Plant Responses to CO_2 – C_3 Plants



Acock, 1990

Direct effect of CO_2 on canopy or Microclimate Soybean Face Experiments



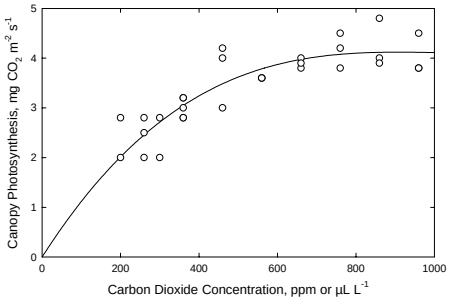
Atmospheric CO2 and Plant Responses

Of the 250,000 higher plant species:

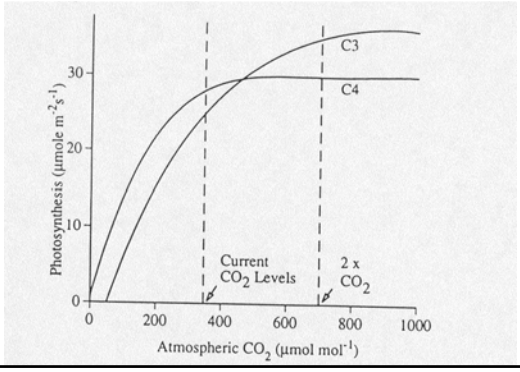
C_3 photosynthetic model	222,000 (89%)
C_4 photosynthetic model	8,000 (3.2%)
Crassulacean Acid Metabolic (CAM) photosynthetic model	20,000 (8%)

Crop Responses to Atmospheric Carbon Dioxide

C_3 example, cotton response



Carbon Dioxide and Photosynthesis Species Variability



Plant Adaptations to Atmospheric Carbon Dioxide

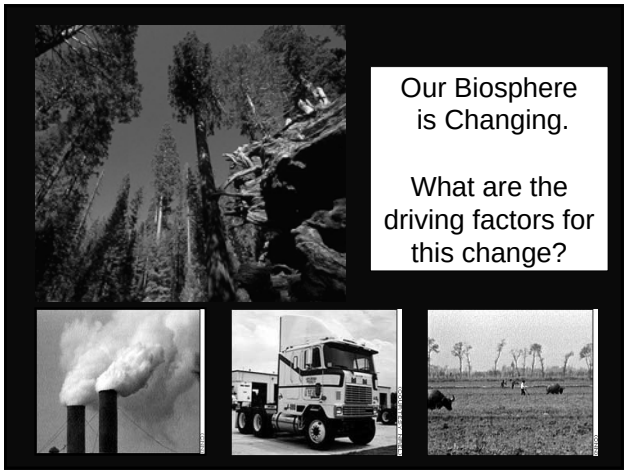
Direct effect of increased CO_2 on crop photosynthesis might lead to higher global food production

- Weeds: Plants are NOT unique and UNIFORM in stimulation of their photosynthesis by elevated CO_2.
- Losses to Pests: Several recent studies show that insects eat more high-CO_2 grown material, because of decreased protein levels.
- Climate: The connection between CO_2 and climate is increasingly well understood, with vast majority of evidence indicating that continued build up of these radiative gases causes gradual warming.

Plant Adaptations to Atmospheric Carbon Dioxide Natural Ecosystems

In natural ecosystems, elevated CO_2 has an effect similar to that on crops; but the responses tend to be smaller or even absent. And, features like:

- Recreational value: Since responses are NOT uniform; there will be winners and losers. Evidence suggest that trees and may be introduced species are being favored in a high-CO_2 world, thus affecting the recreational and grazing value.
- Biodiversity: Rare or endemic species may be at a disadvantageous position because of their poorly adapted features.



Trends, Signs and Signatures from the Earth
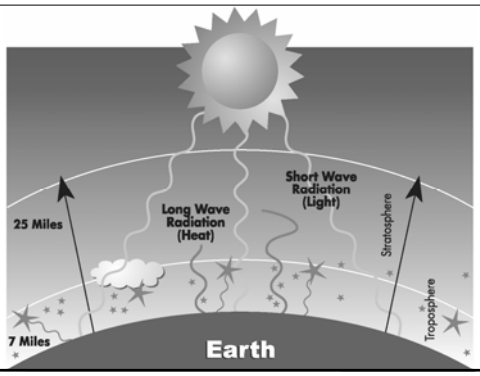
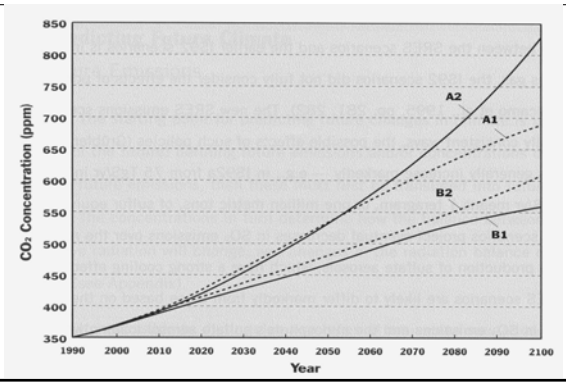
Greenhouse gases and Climate Change



Trends, Signs and Signatures from the Earth
Projected Global Carbon Dioxide Concentrations



Trends, Signs and Signatures from the Earth
Future trends in global carbon dioxide concentration and associated climate change, if no interventions are made

Climate variable	**2025**	**2050**	**2100**
Carbon dioxide concentration	405-460 ppm	445-640 ppm	540-970 ppm
Global mean temperature change from the year 1990	0.4-1.1 ^{o}C	0.8-2.6 ^{o}C	1.4-5.8 ^{o}C
Global mean sea-level rise from the year 1990	3-14 cm	5-32 cm	9-88 cm

Predicted Annual Temperature Increase in GCMs for Doubled CO_2 Scenario

(Adams et al., 1990)

Region	GISS	GFDL
	°C	
Southeast	3.5	4.9
Delta	5.3	4.4
Northern Plains	4.7	5.9
Southern Plains	4.4	4.5
Mountain	4.9	5.3
Pacific	4.7	4.7

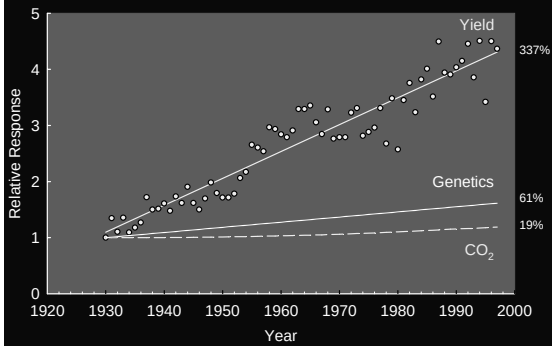
Relative Responses



Summary

- CO_2 is a critical component of the atmosphere.
- Increases in CO_2 will have both positive and negative impacts on agriculture and natural ecosystems.
- The negative impacts expressed through climate change and global warming affect not only agriculture but also other sectors.
- Overall, increasing CO_2 is likely to cause serious problems.
- It is extremely unlikely that terrestrial uptake of CO_2 will be sufficient to prevent these climate problems.
- A major adaptive response will be breeding or designing new cultivars: heat-and-cold and drought resistance crop varieties that may be better adapted to new climate (short-term fixes).
- Additional steps to limit CO_2 emission by world's nations is another possibility (long-term strategies).
