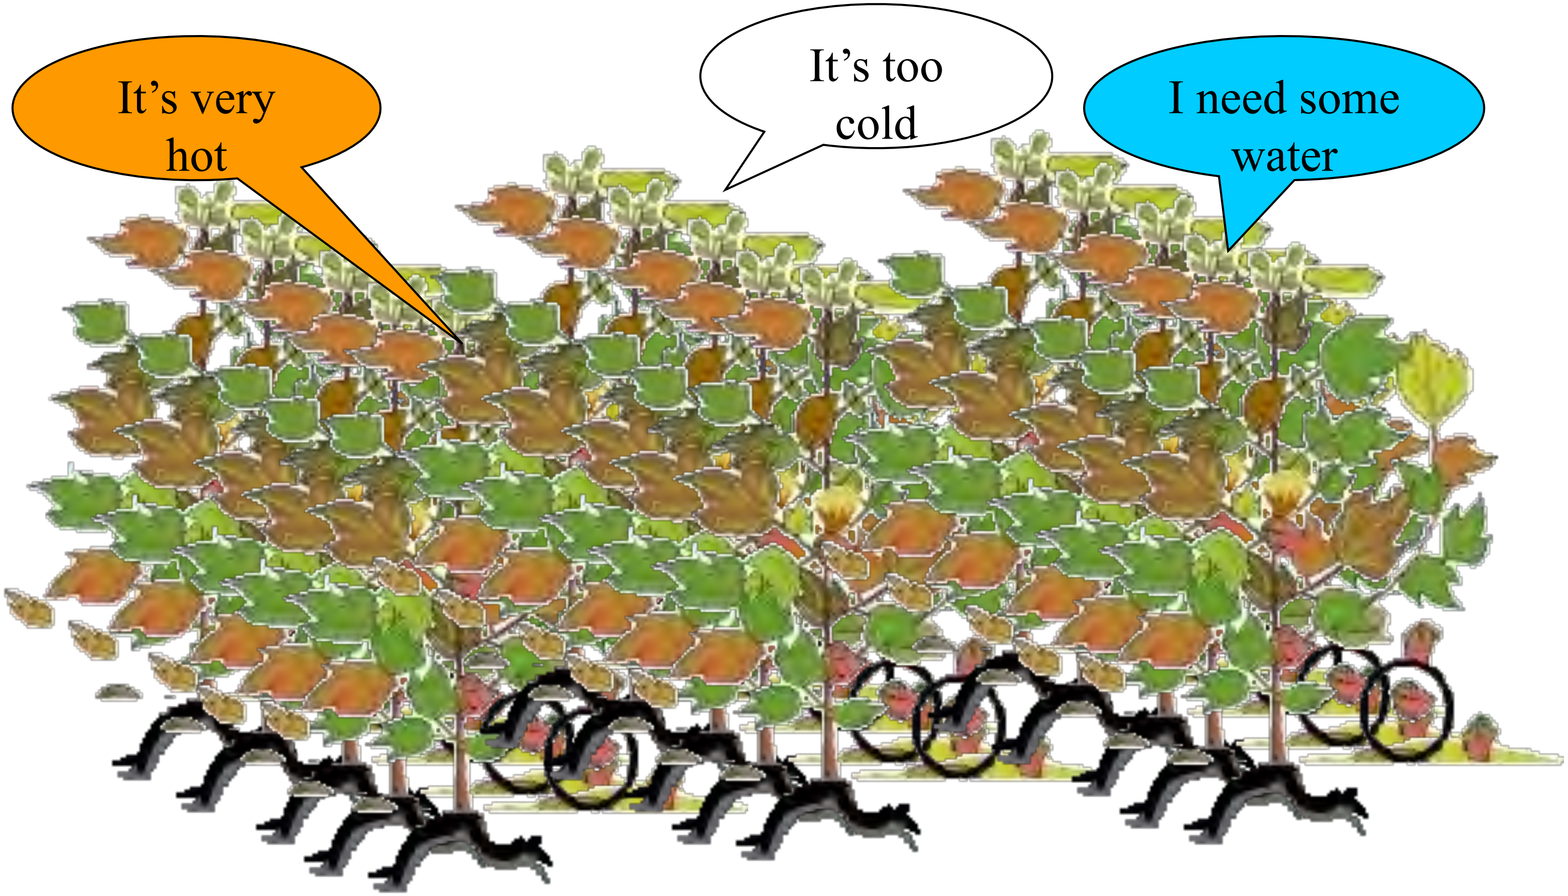
Plant Responses to Extreme Temperatures



Plants lack locomotion

They should either adapt or tolerate stress

Plant Responses to Extreme Temperatures

- Few plant species survive a steady high temperatures above 45 °C

  ✓ Actively growing tissues can rarely survive over 45°C

  ✓ However, non-growing cells or organs (Pollen and seed) can survive much higher temperatures.

  - some pollen up to 70 °C
  - some seed up to 120 °C.

- Heat stress is also a major problem in greenhouses, where low air speed and high humidity decreases leaf cooling and thus affecting leaf/canopy temperatures.

Plant Responses to Extreme Temperatures

- Plants do adapt to high temperature:
  - ✓ Reflective leaf hairs and waxes
  - ✓ Leaf rolling, and vertical leaf orientation
  - ✓ Small leaves and dissected (okra) leaf morphology
  - ✓ Synthesis of heat-shock proteins (HSPs)
    - ⇨ Help cells withstand heat stress
    - ⇨ However, the functions of all HSPs are not yet fully known, but many act as molecular chaperons, help stabilize and fold proteins, assist in polypeptide transport across membranes, protect enzymes, etc.

Plant Critical Processes at Extreme Temperatures

- Photosynthesis and respiration, and conductivity will be affected by high temperatures.
- However, photosynthesis declines faster than respiration and conductivity at high temperatures.
- The point when the amount of CO_2 fixed equals to the amount of CO_2 released by respiration is called temperature compensation point. At this point and beyond, the carbon is not replaced, and carbohydrate reserves will be used for cellular functions.
- Therefore, the imbalance between photosynthesis and respiration causes deleterious effects at high temperatures.

Plant Critical Processes at Extreme Temperatures

- The question is how do plant groups respond to high temperatures?
- Enhanced temperatures are more detrimental in C_3 plants than in C_4 or CAM plants because of rates of both dark and photorespiration are increased more in C_3 plants.
- What happens to C_3 plants under elevated CO_2 conditions?

Climate Change and Crop Production

- Past changes in greenhouse gases has resulted about 0.6 °C increase in global average temperature during the last century.
- If current and future rates of changes in greenhouse gases and other land-use changes continue, then, these changes will exacerbate the natural climate changes and may result in:

    - 2 to 6 °C warmer temperatures

    - More frequent episodes of extreme events (heat, cold, drought, excessive rainfall resulting in floods, severe hurricanes, etc.).

Second green revolution to overcome environmental stresses

5 bolls per plant with 6 g per boll will yield 1.98 bales per acre

High Temperature Effects on Cotton Fruit Production and Retention

Pima Cotton Responses to Temperatures

The next 3 video clips show cotton responses to optimum (30/22°C, day/night), higher (35/27°C) and super-optimum (40/32°C) temperatures.

Notice that the plants grown in optimum temperatures are producing both vegetative and reproductive structures continuously and there is no abscission of squares or fruiting structures. Plants grown in 35/27°C are producing luxuriant vegetative growth, but some of the squares are being abscised due to excessive heat. If plants are grown in 40/32°C, the vegetative growth is reduced to certain extent compared to plants grown in other temperatures, but there is a complete reproductive failure (no flower-bud initiation and even fruiting branch production) due to excessive heat.

Optimum Temperature
No Injury to Reproductive Parts

Higher Temperature Injury
Partial Injury to Reproductive Parts

Super High Temperature Injury

Total Reproductive Failure, Including Fruiting Branch Production

High Temperature Effects on Cotton – Upland Cotton

High Temperature Effects on Cotton

Heat-blasted Flowers – San Joaquin Valley, California, USA

High Temperature Effects on Cotton

The high temperature injury in cotton to reproductive growth and development is not fully understood so for.

High temperature causes some heat-sensitive cultivars/species (Pima cotton) to be vegetative (total reproductive failure and the reproductive induction process is sensitive). Not much is known why plants stay vegetative at those high temperature conditions.

Once the flower-buds (squares) are formed, exposure to extremely high temperatures (35/27^{o}C) will result in abscission of squares.

High Temperature Effects on Cotton

Nutrient starvation is not the factor that causes that square abortion because plants grown in elevated or twice ambient CO_2 and under optimum nutrient conditions also drop those squares, and the nutrient demand for squares is minimal.

The evidence suggest that the 2 weeks prior to and 1 week post flower is the most sensitive stage in cotton.

Systematic evaluation is needed to quantify the effects of high temperature on both the male (anther, pollen growth and development) and female (ovule growth and development).

High Temperature Effects on Cotton

Breeders need simple and quantitative methods to screen genotypic variability and to find or breed a genotype to a niche environment for optimum crop production.

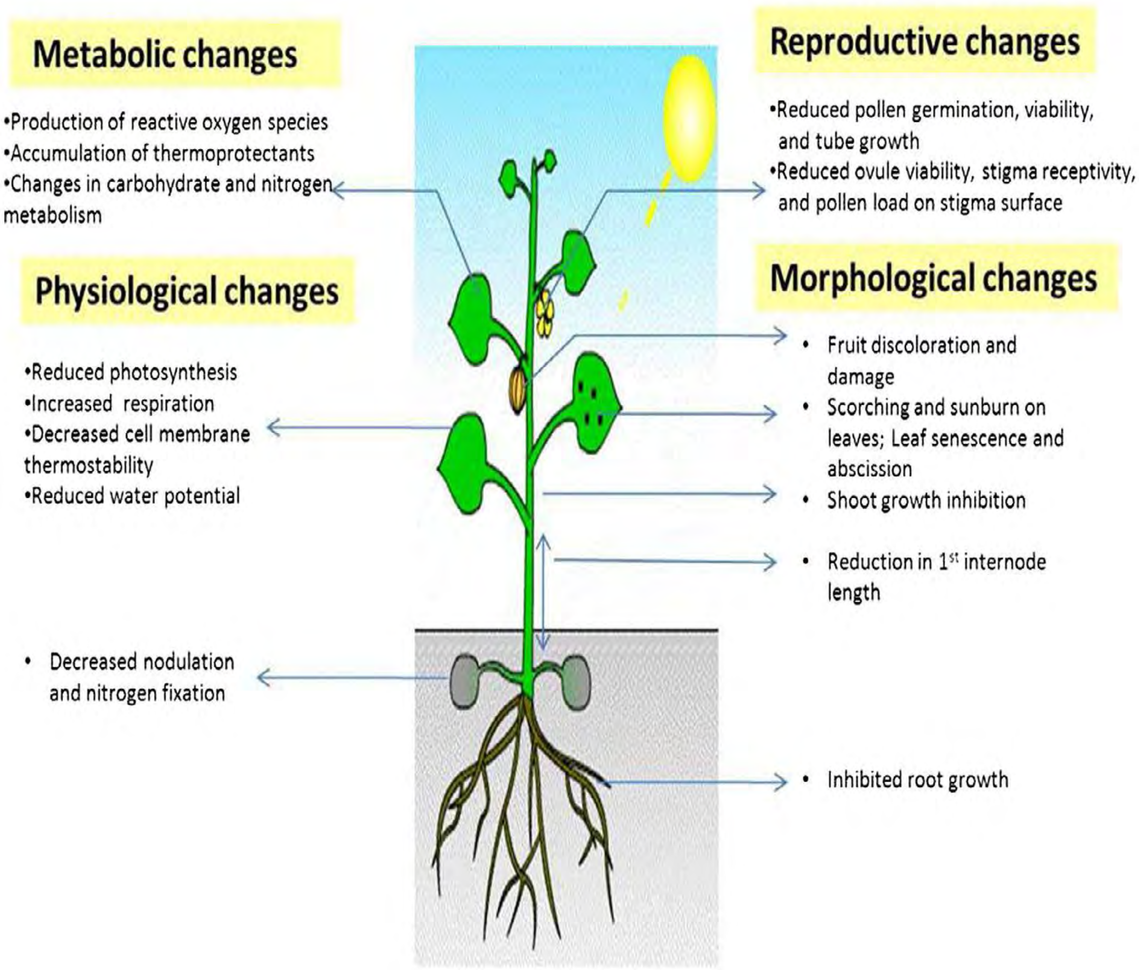
Biotechnology may play a role in developing cultivars that are more heat-tolerant.

Heat-tolerance will be beneficial even in today's environment, and will be needed more in a warmer future climatic conditions.

High Temperature Target Sites in Plants

Morphological, physiological, metabolic, and reproductive changes in plants under heat stress.

(1) *Direct injury*: includes aggregation and denaturation of proteins as well as increased fluidity of membranes.
(2) *Indirect injury*: includes inactivation of enzymes in chloroplasts and mitochondria, inhibition of protein synthesis, enhanced protein degradation and loss of membrane integrity.
All these alterations result in cell injury or even death within a few minutes, which ultimately leads to catastrophic collapse of cellular organization



Kaushal et al., *Cogent Food & Agriculture* (2016), 2: 1134380

http://dx.doi.org/10.1080/23311932.2015.1134380

High Temperature Target Sites in Plants

Both microgametophyte and megagametophyte are the main target sites of heat stress, with the former more heat sensitive.

High Temperature Effects on Reproductive and Grain-filling Stages

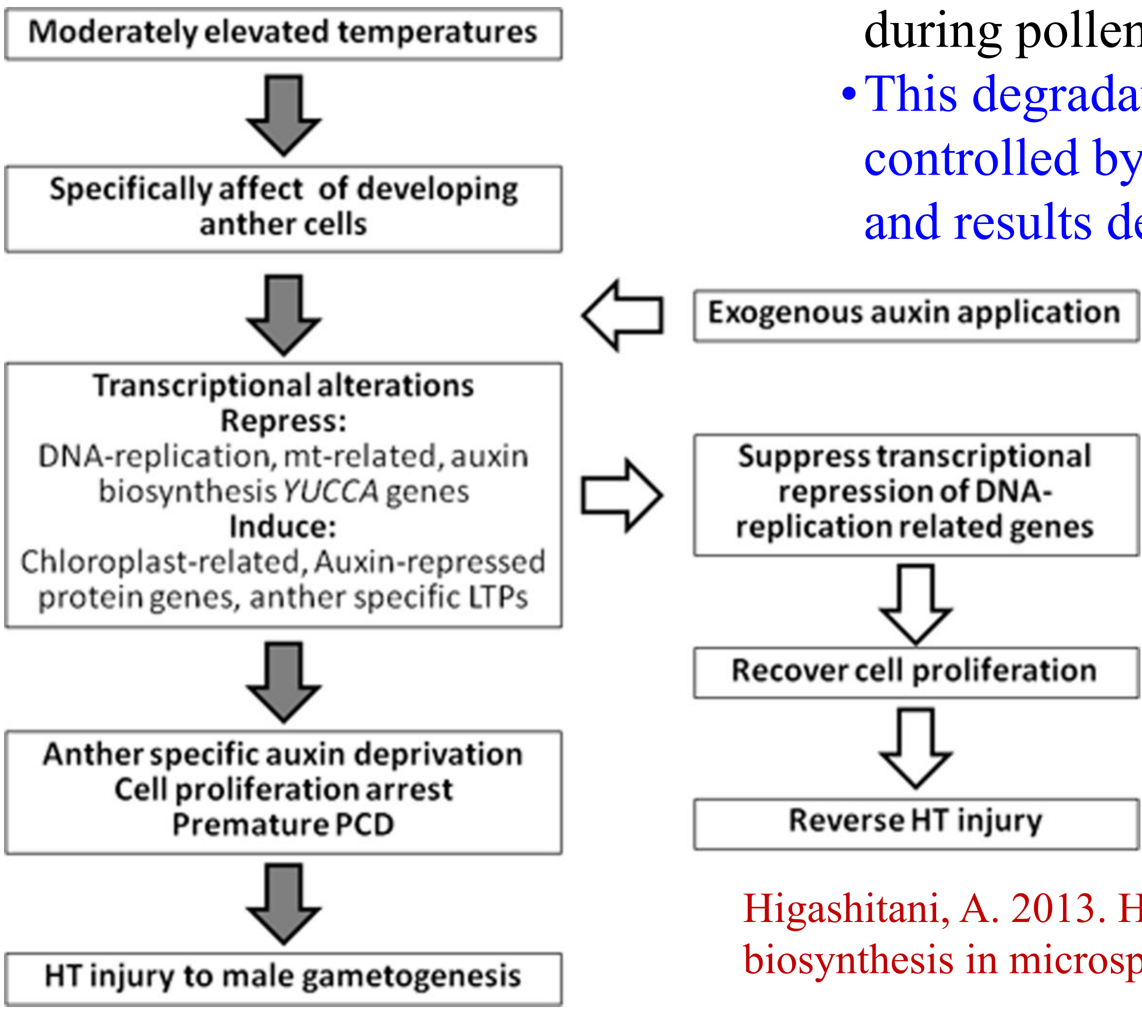
Summary of HT injury to anther early development and effect of exogenous application of auxin.



- The four differentiated layers of anther wall cells (epidermal, endothecium, middle layer, and tapetum cells) are sequentially degraded during pollen maturation.
- This degradation process appears to be controlled by programmed cell death (PCD) and results dehiscence of anther walls.

High Temperature

Effects on Growth Stages of Major Crops

Table 3.4 High temperature effects on growth stages of major crops (from Acock and Acock, 1993)

Crop	Effects
Wheat	Temperature >30°C for >8 h, can reverse vernalization
Rice	Temperature >35°C for >1 h at anthesis causes spikelet sterility
Maize	Temperature >36°C causes pollen to lose viability
Soybean	Great ability to recover from stress. No especially critical period in its development
Potato	Temperature >20°C depresses tuber initiation and bulking
Cotton	Temperature >40°C for >6 h causes bolls to abort

High Temperature Injury
Conclusions – Temperature and CO2 Interactions

- There are no beneficial effects of elevated CO_2 on reproductive processes.
- There are no beneficial interaction of CO_2 on temperature effects on reproductive processes and yield.
- Negative effects of elevated temperature on seed set, seed yield and harvest index were greater at elevated CO_2 (grain sorghum, dry bean and big blue stem).

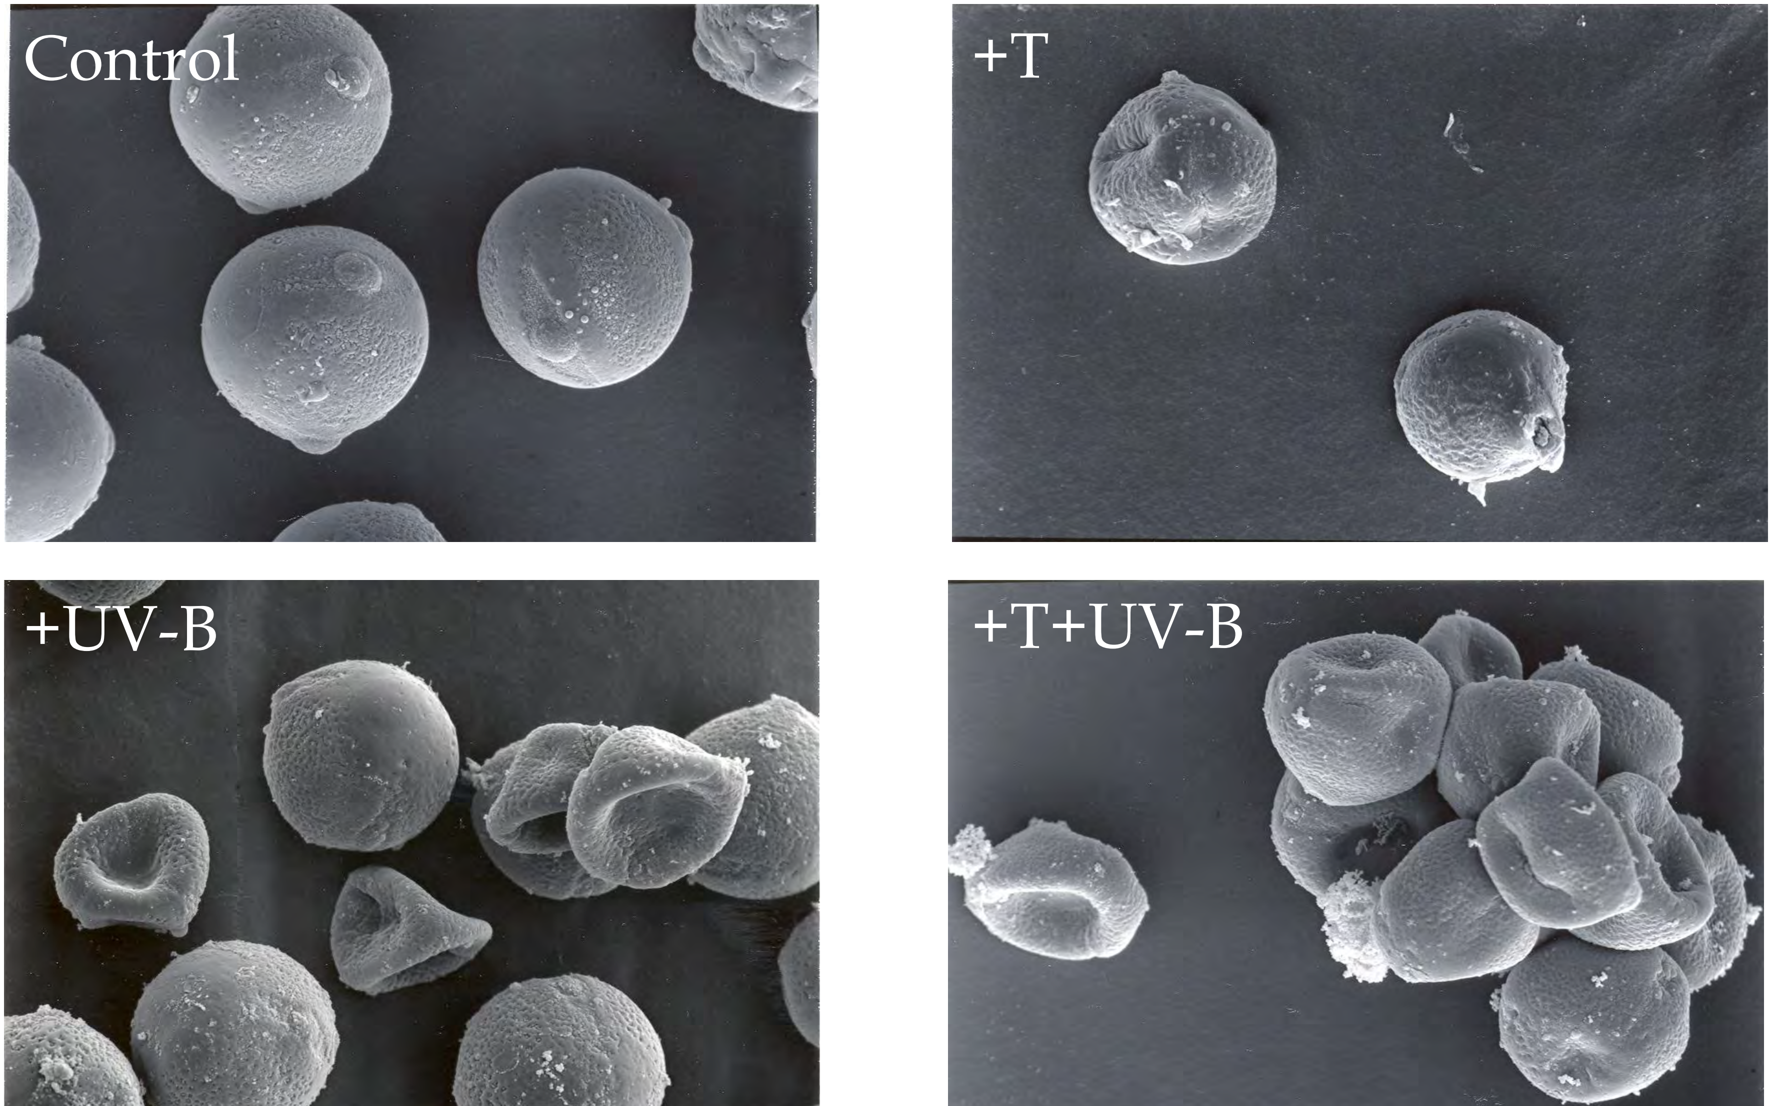
UV-B and Temperature

Soybean Reproductive Development – Sensitive Cultivar



Climate Change and Crop Productivity

Conclusions – Temperature and CO2 Interactions

- There are no beneficial effects of elevated CO_2 on reproductive processes in the crops investigated (cotton, soybean, rice, sorghum and beans).
- There are no beneficial interaction of temperature on UV-B effects on reproductive processes.
- High temperatures and higher UV-B aggravated the damaging effect on many reproductive processes.
- Elevated CO_2 did not ameliorate the damaging effects of either higher temperatures or elevated UV-B levels.

High Temperature Injury – Crop Reproduction Concluding Remarks

- The influence of stress factors on reproductive biology of crops/plants has not been well studied.
- Better screening tools/methods are needed to assess the genotypic variability among crop species.
- The current rate of climate change and climate variability and projected changes in climate are unprecedented, and plants may not cope with these rapid changes.
- There is an urgent need to develop crop cultivars to a variety of stresses (high and low temperatures, water/drought stress, salt stress, UV-B radiation stress etc. either alone or in combination).
